

Question ID: 22105871

Question

Text 1

In a study of insect behavior, Samadi Galpayage and colleagues presented bumblebees with small wooden balls and observed many of the bees clinging to, rolling, and dragging the objects. The researchers provided no external rewards (such as food) to encourage these interactions. The bees simply appeared to be playing—and for no other reason than because they were having fun.

Text 2

Insects do not have cortexes or other brain areas associated with emotions in humans. Still, Galpayage and her team have shown that bumblebees may engage in play, possibly experiencing some kind of positive emotional state. Other studies have suggested that bees experience negative emotional states (for example, stress), but as Galpayage and her team have acknowledged, emotions in insects, if they do indeed exist, are likely very rudimentary.

Based on the texts, how would the author of Text 2 most likely respond to the underlined portion of Text 1?

Answer

- A. By objecting that the bees were actually experiencing a negative feeling akin to stress rather than a positive feeling
- B. By arguing that some insects other than bumblebees may be capable of experiencing complex emotional states
- C. By pointing out that even humans sometimes struggle to have fun while engaging in play
- D. By noting that if the bees were truly playing, any positive feelings they may have experienced were probably quite basic
